Abstract. The Rhesus Monkey Brain in Stereotaxic Coordinates is the most comprehensive, detailed atlas of the monkey brain ever constructed. The first chapter, "Photographic and Diagrammatic Atlas of the Rhesus Monkey Brain," presents 151 plates illustrating the subcortex and parts of the cortex in high magnification, and 151 corresponding diagrams complementing each image.

It is well known that dopamine (DA) is critical for reward, but the precise role of DA in reward remains uncertain. The aim of this study was to determine what percentage of dopaminergic neurons in the primate brain is required for the expression of conditioned reward by measuring the performance of DA-deficient rhesus monkeys in a morphine-induced conditioned place preference (CPP) paradigm.

In the rhesus monkey, the CC interconnects the frontal, parietal, temporal, and occipital cortices with more than 56 million callosal fibers (LaMantia and Rakic 1990b). Using light and electron microscopy LaMantia and Rakic (1990a , 1990b) described a mosaic-like fiber system in the CC of the rhesus macaque and a region-specific organization into 10 subregions along the anterior-posterior axis.
