## **P-Value Definition**

The p-value is a number between 0 and 1 and interpreted in the following way: A small p-value (typically  $\leq 0.05$ ) indicates

strong evidence against the null hypothesis, so you reject the null hypothesis. A large p-value ( $> 0.05$ ) indicates weak evidence against the null hypothesis, so you fail to reject the null hypothesis.

In null hypothesis significance testing,

the p-value is the probability of obtaining test results at least as extreme as the results actually observed, under the assumption that the null hypothesis is correct. A very small p-value means that such an extreme observed outcome would be very unlikely under the null hypothesis.

## **p-value - Wikipedia**

A p-value is the

probability that, if the null hypothesis were true, we would observe a statistic at least as extreme as the one observed. To calculate a p-value we use the appropriate software or statistical table that corresponds with our test statistic.

In statistical hypothesis testing, the p-value or probability value is, for

a given statistical model, the probability that, when the null hypothesis is true, the statistical summary (such as the absolute value of the sample mean difference between two compared groups) would be greater than or equal to the actual observed results.

P-value does not hold any value by itself. A large p-value implies that sample scores are more aligned or similar to the population score. It is as simple as that. Now, you might have come across the thumb rule of comparing the p-value with the alpha value to draw conclusions.

The p-value is conditional upon the null hypothesis being true is unrelated to the truth or falsity of the research hypothesis. A p-value higher than 0.05 ( $> 0.05$ ) is not statistically significant and indicates strong evidence for the null hypothesis. This means
